

VERSION 1 · RETAINED MECHANISM AND CLAIM BOUNDARY

The V1 mechanism remains; its paper needs precise corrections

Version 1's EETF, VCC, reward, scarcity, and exclusion mechanism is retained. Its universal-agent wording, potentially ambiguous use of “penalty,” and printed indifference formula are superseded by the scoped theorem below.

Retained Version 1 result

Let M be the scarcity multiplier, R the funded direct-reward coefficient, L the scarcity-upside coefficient available only to an EETF-eligible branch, and G the bounded deviation gain available to the excluded branch. If exclusion is enforceable and $G < M(R+L)$, every exact maximizer over the declared alternatives selects eligibility. For integers with $R+L > 0$, the least multiplier is $\text{floor}(G/(R+L)) + 1$. The standalone proof is in `proofs/v1/AlignmentTheoremV1.lean`.

Exclusion is opportunity cost

The historical presentation placed $M \cdot L$ as a negative term on the excluded branch. Adding $M \cdot L$ to both alternatives gives the equivalent normalized comparison $M(R+L) > G$. No tax, fine, burn, confiscation, or balance debit is applied to the excluded actor. The load-bearing premise is that the actor genuinely cannot obtain the protected scarcity upside. Upside shared by both branches cancels.

Separate Version 1.1 result

Version 1.1 generalizes the concrete V1 mechanism under the conditional strict margin $M(t)K(t) > B(t)$. It proves the utility-bound implication, the exact least integer threshold, a bounded-deviation asymptotic result, and a relative-growth result. The conclusion applies only to the declared two-action model and authenticated external assumptions.

Read the [Version 1.1 paper](#) or the [Version 1.1 PDF](#), and see the [current Tau integration matrix](#) for all three profiles.

Provenance

The uncorrected 16-page [original academic paper](#) is preserved as a historical artifact from Git commit a28695f. Its SHA-256 is f5dca5a1e7bcd069441f16410664cdecac3eebe4a5af8f128dd0efa7043c8bc. Read it together with this claim boundary: the original wording is provenance, while the reconstructed theorem states the current checked claim.
